

# Spherical varieties

Jackson Van Dyke

Monday July 13, 2020

But first... 😊

Our building will officially be renamed  
“PMA”! 😊

See [here](#) for the full announcement.

# Table of contents

- 1 Motivation
  - What are they?
  - What are they good for?
- 2 Reductive groups
  - A trip to the zoo
  - Representation theory of reductive groups
- 3 Spherical varieties
  - Equivalent definitions of spherical varieties
  - Good features

- $k$  is a field.
- $G$  is an algebraic group over  $k$  (an algebraic variety which is also a group).
- $X$  is an algebraic variety over  $k$  equipped with an action of  $G$ .

# Map of the zoo

## Definition (solvable)

An algebraic group  $G$  is *solvable* if and only if it admits a subnormal series

$$G = G_0 \supset G_1 \supset \cdots \supset G_k = \{1\} \quad (1)$$

such that each  $G_i/G_{i+1}$  is abelian. In other words it is built out of abelian groups by extensions.

# Simple, semisimple, and reductive

The *radical* of  $G$ , written  $R(G)$ , is the maximal normal subgroup which is connected, and solvable.

(Such a subgroup exists because extensions and quotients of solvable algebraic groups are solvable.)

## Definition 1 (simple)

$G$  is *simple* if and only if it does not contain any (proper, nontrivial, and connected) normal subgroups.

## Definition 2 (semisimple)

$G$  is *semisimple* if and only if  $R(G) = \{1\}$ .

## Definition 3 (reductive)

$G$  is *reductive* if and only if  $R(G) \cong (\mathbb{C}^\times)^n$  for some  $n$ .

- Simple** = no normal subgroups; (2)
- semisimple** = no solvable normal subgroups; (3)
- reductive** = solvable normal subgroups are abelian. (4)

# First observations

- Simple  $\implies$  semisimple  $\implies$  reductive.
- $G/R(G)$  is always semisimple.
- If  $G$  is abelian then  $G$  is reductive.
- If  $G$  is solvable and nonabelian then  $G$  is not reductive.
- If  $G$  is unipotent then  $G$  is not reductive.

# Unipotent characterization

Recall an operator  $T$  is called *unipotent* if and only if there is some  $N \in \mathbb{Z}_+$  such that

$$(T - 1)^N = 0 . \quad (5)$$

An algebraic group is called *unipotent* if it acts by unipotent operators in any rational representation.

## Fact 1

*$G$  is reductive if and only if it does not contain any normal subgroups which are (proper, connected, and) unipotent.*

Just as  $G/R(G)$  was semisimple, the quotient of any algebraic group by its maximal normal subgroup which is (connected and) unipotent is reductive.

# Examples of reductive algebraic groups

## Example 1

$(\mathbb{C}^\times)^n$  is reductive.

## Example 2

The algebraic groups

- $\mathrm{SL}_n$  (for  $n \geq 2$ ),
- $\mathrm{Sp}_{2n}$ , and
- $\mathrm{SO}_n$  (for  $k = \overline{k}$ )

are all simple, so reductive.

## Example 3

$\mathrm{GL}_n$  and  $\mathrm{O}_n$  are reductive.

# Examples which are not reductive

## Example 4

The additive group, and product of it, are not reductive. This is because we can view  $a \in \mathbb{G}_a$  as

$$\begin{bmatrix} 1 & a \\ 0 & 1 \end{bmatrix}. \quad (6)$$

So this is actually an unipotent group, and therefore cannot be reductive.

## Example 5

The Borel subgroup  $B$  of  $GL_n$  is not reductive. This consists of upper triangular matrices, and has nontrivial unipotent normal subgroup consisting of upper-triangular matrices with 1 on the diagonal.

# Example of semisimple quotient

The following is from [Mil]. Consider the algebraic group  $\mathrm{GL}_{m+n}$ . This is given by block matrices

$$\begin{bmatrix} A & B \\ 0 & C \end{bmatrix} \quad (7)$$

where  $A$  is  $m \times m$  and  $C$  is  $n \times n$ .

The radical consists of matrices of the form:

$$\begin{bmatrix} aI_m & B \\ 0 & cI_n \end{bmatrix} \quad (8)$$

and the semisimple quotient is:

$$G/R(G) = \mathrm{PGL}_m \times \mathrm{PGL}_n . \quad (9)$$

# Semi-simple representations

A semisimple (or completely reducible) representation is a direct sum of simple (or irreducible) representations.

[link](#)

[wikipedia](#)

# Rep. theoretic characteristic of being reductive

## Theorem

*Assume  $\text{char } k = 0$ .  $G$  is reductive iff every representation is semisimple.*

The direction ( $\Leftarrow$ ) is easy to show. Normal unipotent subgroups of  $G$  act trivially on semisimple representations of  $G$ . So if  $G$  admits a faithful semisimple representation then  $G$  is reductive.

# Usual definition of spherical varieties

## Definition (spherical variety)

$X$  is a *spherical variety* if and only if it contains an open dense  $B$  orbit.

Now we will identify some equivalent characterizations of spherical varieties. The punchline will be that this is fundamentally some kind of finiteness condition.

## Definition (complexity)

The complexity of  $X$ , written  $c(X)$ , is the minimal codimension of a  $B$  orbit.

## Theorem 1

$X$  is spherical if and only if  $c(X) = 0$ .

## Proof.

Open dense orbits are the proper codimension 0 orbits. □

# Finitely many $B$ orbits

## Theorem 2

*$X$  is spherical if and only if it has finitely many  $B$  orbits.*

## Lemma 2 (Theorem 4.5.5 [Per])

*If  $Y \subset X$  is a closed  $B$ -stable subvariety then  $c(Y) \leq c(X)$ .*

## Proof.

( $\implies$ ): Let  $Y \subseteq X$  be some minimal subvariety containing infinitely many orbits. Lemma 2 implies  $c(Y) = 0$ . The complement of this orbit is a closed  $G$ -stable subvariety which must have infinitely many  $B$ -orbits, contradicting minimality of  $Y$ .

( $\impliedby$ ): Nonzero complexity implies infinitely many  $G$  orbits (and hence  $B$  orbits) since any maximal orbit has nonzero codimension, and orbits are disjoint. □

# Borel invariant rational functions

## Theorem 3

*$X$  is spherical if and only if the only  $B$  invariant rational functions are constant:  $k(X)^B = k$ .*

This follows from Rosenlicht's theorem [Ros63] Theorem 2.3.

## Theorem (Rosenlicht)

*The transcendence degree of  $k(X)^B$  over  $k$  is  $c(X)$ .*

The idea is that

$$c(X) = \dim("X/B") \quad (10)$$

$$= \text{transcendence degree}(k("X/B")) \quad (11)$$

$$= \text{transcendence degree}(k(X)^B) . \quad (12)$$

So  $c(X) = 0$  if and only if  $k(X)^B = k$ .

# Tldr (equivalent definitions of spherical varieties)

## Theorem

*The following are equivalent:*

- *$X$  is spherical (i.e.  $X$  contains an open dense  $B$  orbit),*
- *$c(X) = 0$  (i.e. the maximal  $B$  orbit is codimension 0),*
- *$X$  has finitely many  $B$  orbits,*
- *$k(X)^B = k$ .*
